

ARCHER Single Node Optimisation

Optimising with the compiler

Slides contributed by Cray and EPCC

Overview

- Introduction
- Optimisation techniques
 - compiler flags
 - compiler hints
 - code modifications
- Optimisation topics
 - locals and globals
 - conditionals
 - data types
 - CSE
 - register use and spilling
 - loop unrolling/pipelining
 - inlining

Introduction

- Unless we write assembly code, we are always using a compiler.
- Modern compilers are (quite) good at optimisation
 - memory optimisations are an exception
- Usually much better to get the compiler to do the optimisation.
 - avoids machine-specific coding
 - compilers break codes much less often than humans
- Even modifying code can be thought of as "helping the compiler".

Compiler flags

- Typical compiler has hundreds of flags/options.
 - most are never used
 - many are not related to optimisation
- Most compilers have flags for different levels of general optimisation.
 - · -01, -02, -03,....
- When first porting code, switch optimisation off.
 - only when you are satisfied that the code works, turn optimisation on, and test again.
 - but don't forget to use them!
 - also don't forget to turn off debugging, bounds checking and profiling flags...

Compiler flags (cont.)

- Note that highest levels of optimisation may
 - break your code.
 - give different answers, by bending standards.
 - make your code go slower.
- Always read documentation carefully.
- Isolate routines and flags which cause the problem.
 - binary chop
 - one routine per file may help

Compiler flags (cont.)

- Many compilers are designed for an instruction set architecture, not one machine.
 - flags to target ISA versions, processor versions, cache configurations
 - defaults may not be optimal, especially if cross-compiling
- Some optimisation flags may not be part of -On
 - check documentation
 - use sparingly (may only be beneficial in some cases)

Compiler hints

- A mechanism for giving additional information to the compiler, e.g.
 - values of variables (e.g. loop trip counts)
 - independence of loop iterations
 - independence of index array elements
 - aliasing properties
- Appear as comments (Fortran), or preprocessor pragmas
 (C)
 - don't affect portability

Incremental compilation

- Compilers can only work with the limited information available to them.
- Most compilers compile code in an incremental fashion
 - Each source file is compiled independently of each other.
 - Most compilers ignore all source files other than those specified on the command line (or implicitly referenced via search paths, e.g. include files)
 - Routines from other source files treated as "black-boxes"
 - Make worst case assumptions based on routine prototype.
- You can help by providing more information
 - Information in routine prototypes
 - INTENT, PURE, const, etc.
 - Compiler hints
 - Command line flags

Code modification

- When flags and hints don't solve the problem, we will have to resort to code modification.
- Be aware that this may
 - introduce bugs.
 - make the code harder to read/maintain.
 - only be effective on certain architectures and compiler versions.
- Try to think about
 - what optimisation the compiler is failing to do
 - what additional information can be provided to compiler
 - how can rewriting help

- How can we work out what the compiler has done?
 - eyeball assembly code
 - use diagnostics flags
- Increasingly difficult to work out what actually occurred in the processor.
 - superscalar, out-of-order, speculative execution
- Can estimate expected performance
 - count flops, load/stores, estimate cache misses
 - compare actual performance with expectations

Locals and globals

- Compiler analysis is more effective with local variables
- Has to make worst case assumptions about global variables
- Globals could be modified by any called procedure (or by another thread).
- Use local variables where possible
- Automatic variables are stack allocated: allocation is essentially free.
- In C, use file scope globals in preference to externals

Conditionals

- Even with sophisticated branch prediction hardware, branches are bad for performance.
- Try to avoid branches in innermost loops.
 - if you can't eliminate them, at least try to get them out of the critical loops.

```
do i=1,k
  if (n .eq. 0) then
    a(i) = b(i) + c
  else
    a(i) = 0.
  endif
end do
```

```
if (n .eq. 0) then
  do i=1,k
    a(i) = b(i) + c
  end do
else
  do i=1,k
    a(i) = 0.
  end do
endif
```

A little harder for the compiler.....

```
do i=1,k
  if (i .le. j) then
    a(i) = b(i) + c
  else
    a(i) = 0.
  endif
end do
```

Data types

- Performance can be affected by choice of data types
 - often a difference between 32-bit and 64-bit arithmetic (integer and floating point).
 - complicated by trade-offs with memory usage and cache hit rates
- Avoid unnecessary type conversions
 - e.g. int to long, float to double
 - N.B. some type conversions are implicit
 - However sometimes better than the alternative e.g.
 - Use DP reduction variable rather than increase array precision.

CSE

- Compilers are generally good at Common Subexpression Elimination.
- A couple of cases where they might have trouble:

Different order of operands

$$d = a + c$$

 $e = a + b + c$

Function calls

CSE including function calls.

- To extract a CSE containing a function call the compiler has to be sure of various things:
 - The function always returns the same value for the same input.
 - The function does not cause any side effects that would be effected by changing the number of times the function is called:
 - Modifying its inputs.
 - Changing global data.
- Need to be very careful with function prototypes to allow compiler to know this.

Register use

- Most compilers make a reasonable job of register allocation.
 - But only limited number available.
- Can have problems in some cases:
 - loops with large numbers of temporary variables
 - such loops may be produced by inlining or unrolling
 - array elements with complex index expressions
 - can help compiler by introducing explicit scalar temporaries, most compilers will use a register for an explicit scalar in preference to an implicit CSE.

```
tmp = c[0];
for (i=0;i<n;i++) {
    b[i] += a[c[i]];
    c[i+1] = 2*i;
}

tmp = c[0];
for (i=0;i<n;i++) {
    b[i] += a[tmp];
    tmp = 2*i;
    c[i+1] = tmp;
}</pre>
```

Spilling

- If compiler runs out of registers it will generate spill code.
 - store a value and then reload it later on
- Examine your source code and count how many loads/ stores are required
- Compare with assembly code
- May need to distribute loops

Loop unrolling

- Loop unrolling and software pipelining are two of the most important optimisations for scientific codes on modern RISC processors.
- Compilers generally good at this.
- If compiler fails, usually better to try and remove the impediment, rather than unroll by hand.
 - cleaner, more portable, better performance
- Compiler has to determine independence of iterations

Loop unrolling

- Loops with small bodies generate small basic blocks of assembly code
 - lot of dependencies between instructions
 - high branch frequency
 - little scope for good instruction scheduling
- Loop unrolling is a technique for increasing the size of the loop body
 - gives more scope for better schedules
 - reduces branch frequency
 - make more independent instructions available for multiple issue.

Loop unrolling

- Replace loop body by multiple copies of the body
- Modify loop control
 - take care of arbitrary loop bounds
- Number of copies is called unroll factor

Example:

```
do i=1,n-3,4
   a(i)=b(i)+d*c(i)
   a(i+1)=b(i+1)+d*c(i+1)
   a(i+2)=b(i+2)+d*c(i+2)
   a(i+3)=b(i+3)+d*c(i+3)
end do
do j = i,n
   a(j)=b(j)+d*c(j)
end do
```

- Remember that this is in fact done by the compiler at the IR or assembly code level.
- If the loop iterations are independent, then we end up with a larger basic block with relatively few dependencies, and more scope for scheduling.
 - also reduce no. of compare and branch instructions
- Choice of unroll factor is important (usually 2,4,8)
 - if factor is too large, can run out of registers
- Cannot unroll loops with complex flow control
 - hard to generate code to jump out of the unrolled version at the right place

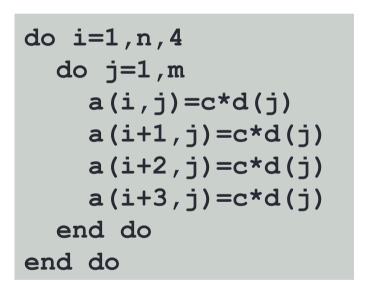

Outer loop unrolling

- If we have a loop nest, then it is possible to unroll one of the outer loops instead of the innermost one.
- Can improve locality.

```
do i=1,n
    do j=1,m
        a(i,j)=c*d(j)
    end do
end do
```

2 loads for 1 flop

5 loads for 4 flops

Variable expansion

- Variable expansion can help break dependencies in unrolled loops
 - improves scheduling opportunities
- Close connection to reduction variables in parallel loops

```
for (i=0,i<n,i++) {
    b+=a[i];
}</pre>
```

```
for (i=0,i<n,i+=2) {
    b+=a[i];
    b+=a[i+1];
}
```

expand b

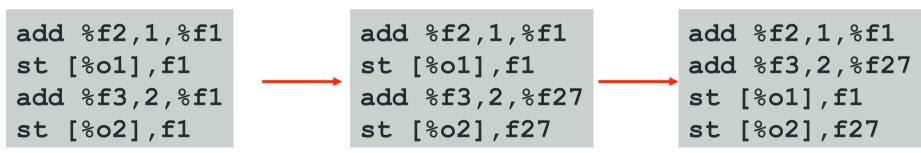

```
for (i=0,i<n,i+=2) {
    b1+=a[i];
    b2+=a[i+1];
}
b=b1+b2;</pre>
```

Register renaming

- Registers may be reused within a basic block introducing unnecessary dependencies.
- Using two (or more) different registers can preserve program correctness, but allow more scheduling flexibility
 - Some CPUs perform register rename and reschedule in hardware, this can utilise additional registers not visible to compiler.

rename

reschedule

Software pipelining

- Problem with scheduling small loop bodies is that there are dependencies between instructions in the basic block.
- Potentially possible to start executing instructions from the next iteration before current one is finished.
- Idea of software pipelining is to construct a basic block that contains instructions from different loop iterations.
 - fewer dependencies between instructions in block
 - needs additional code at start and end of loop

Software pipelining

```
for (i=0;i<n;i++) {
    a(i) += b;
}</pre>
```

```
//prologue
t1 = a(0); //L 0
t2 = b + t1; //A 0
t1 = a(1); //L 1
for (i=0;i<n-2;i++) {
  a(i) = t2; //S i
  t2 = b + t1; //A i+1
  t1 = a(i+2); //L i+2
//epilogue
a(n-2) = t2; //S n-2
t2 = b + t1; //A n-1
a(n-1) = t2; //S n-1
```

At instruction level

```
L: ld [%r1],%f0
fadd f0,f1,f2
st [%r1],f2
add %r1,4,%r1
cmp %r1,%r3
bg L
nop
```

st must wait for fadd to complete: pipeline stall for data hazard

```
ld
        [%r1],%f0
        f0,f1,f2
  fadd
  1d
        [%r1+4],%f0
L: st [%r1],f2
  fadd f0,f1,f2
  ld [%r1+8],%f0
       %r1,%r3-8
  cmp
  bg
  add
        %r1,4,%r1
  st
       [%r1],f2
  add %r1,4,%r1
        f0,f1,f2
  fadd
  st
        [%r1],f2
```

Impediments to unrolling

- Function calls
 - except in presence of good interprocedural analysis and inlining
- Conditionals
 - especially control transfer out of the loop
 - lose most of the benefit anyway as they break up the basic block.
- Pointer/array aliasing
 - compiler can't be sure different values don't overlap in memory

Example

```
for (i=0;i<ip;i++) {
    a[indx[i]] += c[i] * a[ip];
}</pre>
```

- Compiler doesn't know that a[indx[i]] and a[ip] don't overlap
- Could try hints
 - tell compiler that indx is a permutation
 - tell compiler that it is OK to unroll
- Or could rewrite:

```
tmp = a[ip];
for (i=0;i<ip;i++) {
    a[indx[i]] += c[i] * tmp;
}</pre>
```

Inlining

- Compilers very variable in their abilities
- Hand inlining possible
 - very ugly (slightly less so if done via pre-processor macros)
 - causes code replication
- Compiler has to know where the source of candidate routines is.
 - sometimes done by compiler flags
 - easier for routines in the same file
 - try compiling multiple files at the same time
- Very important for OO code
 - OO design encourages methods with very small bodies
 - inline keyword in C++ can be used as a hint

Multiple Optimisation steps

- Sometimes multiple optimisation steps are required.
 - Multiple levels of in-lining.
 - In-lining followed by loop un-rolling followed by CSE.
- The compiler may not be able to perform all steps at the same time
 - You may be able to help the compiler by performing some of the steps by hand.
 - Look for the least damaging code change that allows the compiler to complete the rest of the necessary changes.
 - Ideally try each step in isolation before attempting to combine hand-optimisations.

General Cray Compiler Flags

Optimisation Options

· -O2

· -O3

-O ipaN (ftn) or -hipaN (cc/CC)

optimal flags [enabled by default]

aggressive optimization

inlining, N=0-5 [default N=3]

Create listing files with optimization info

-ra (ftn) or -hlist=a (cc/CC)

-rm (ftn) or -hlist=m (cc/CC)

creates a listing file with all

optimization info

produces a source listing with

loopmark information

Parallelization Options

-O omp (ftn) or -h omp (cc/CC)

 O threadN (ftn) or h threadN (cc/CC) Recognize OpenMP directives [default]

control the compilation and optimization of OpenMP directives, N=0-3 [default N=2]

→ More info: man crayftn, man craycc, man crayCC

Recommended CCE Compilation Options

- Use default optimization levels
 - It's the equivalent of most other compilers -O3 or -fast
 - It is also our most thoroughly tested configuration
- Use -O3,fp3 (or -O3 -hfp3, or some variation) if the application runs cleanly with these options
 - -O3 only gives you slightly more than the default -O2
 - Cray also test this thoroughly
 - -hfp3 gives you a lot more floating point optimization (default is -hfp2)
- If an application is intolerant of floating point reordering, try a lower hfp number
 - Try -hfp1 first, only -hfp0 if absolutely necessary (-hfp4 is the maximum)
 - Might be needed for tests that require strict IEEE conformance
 - Or applications that have 'validated' results from a different compiler
- Do not use too aggressive optimizations, e.g. -hfp4
 - Higher numbers are not always correlated with better performance

OpenMP

- OpenMP is ON by default
 - This is the opposite default behavior that you get from GNU and Intel compilers
 - Optimizations controlled by -OthreadN (ftn) or -hthreadN (cc/CC), N=0-3 [default N=2]
 - To shut off use -O/-h thread0 or -xomp (ftn) or -hnoomp
- Autothreading is NOT on by default
 - -hautothread to turn on
 - Interacts with OpenMP directives
- If you do not want to use OpenMP and have OMP directives in the code, make sure to shut off OpenMP at compile time

CCE – GNU – Intel compilers

- More or less all optimizations and features provided by CCE are available in Intel and GNU compilers
 - GNU compiler serves a wide range of users & needs
 - Default compiler with Linux, some people only test with GNU
 - GNU defaults are conservative (e.g. -O1)
 - -O3 includes vectorization and most inlining
 - Performance users set additional options
 - Intel compiler is typically more aggressive in the optimizations
 - Intel defaults are more aggressive (e.g -O2), to give better performance "out-of-the-box"
 - · Includes vectorization; some loop transformations such as unrolling; inlining within source file
 - Options to scale back optimizations for better floating-point reproducibility, easier debugging, etc.
 - Additional options for optimizations less sure to benefit all applications
 - CCE is even more aggressive in the optimizations by default
 - · Better inlining and vectorization
 - Aggressive floating-point optimizations
 - OpenMP enabled by default
- GNU users probably have to specify higher optimisation levels

Cray, Intel and GNU compiler flags

Feature	Cray	Intel	GNU
Listing	-hlist=a	-opt-report3	-fdump-tree-all
Free format (ftn)	-f free	-free	-ffree-form
Vectorization	By default at -O1 and above	By default at -O2 and above	By default at -O3 or using -ftree-vectorize
Inter-Procedural Optimization	-hwp	-ipo	-flto (note: link-time optimization)
Floating-point optimizations	-hfpN, N=04	-fp-model [fast fast=2 precise except strict]	-f[no-]fast-math or -funsafe-math-optimizations
Suggested Optimization	(default)	-O2 -xAVX	-O2 -mavx -ftree-vectorize -ffast-math -funroll-loops
Aggressive Optimization	-O3 -hfp3	-fast	-Ofast -mavx -funroll-loops
OpenMP recognition	(default)	-fopenmp	-fopenmp
Variables size (ftn)	-s real64 -s integer64	-real-size 64 -integer-size 64	-freal-4-real-8 -finteger-4-integer-8

Summary

- Remember compiler is always there.
- Try to help compiler, rather than do its job for it.
- Use flags and hints as much as possible
- Minimise code modifications
