Introduction to OpenMP

Lecture 6: Further topics in OpenMP

Nested parallelism

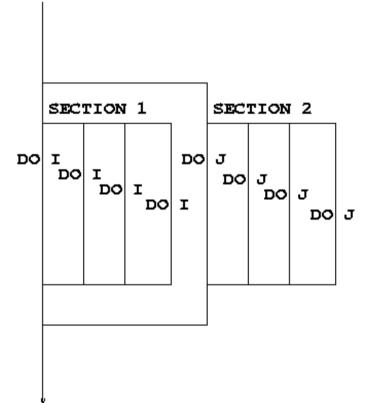

- Unlike most previous directive systems, nested parallelism is permitted in OpenMP.
- This is enabled with the **OMP_NESTED** environment variable or the **OMP_SET_NESTED** routine.
- If a PARALLEL directive is encountered within another PARALLEL directive, a new team of threads will be created.
- The new team will contain only one thread unless nested parallelism is enabled.

Nested parallelism (cont)

Example:	
!\$OMP	PARALLEL
!\$OMP	SECTIONS
!\$OMP	SECTION
!\$OMP	PARALLEL DO
	do $i = 1, n$
	x(i) = 1.0
	end do
!\$OMP	SECTION
!\$OMP	PARALLEL DO
	do $j = 1, n$
	y(j) = 2.0
	end do
!\$OMP	END SECTIONS
!\$OMP	END PARALLEL

Nested parallelism (cont)

- Not often needed, but can be useful to exploit nonscalable parallelism (SECTIONS).
- Note: nested parallelism isn't supported in some implementations (the code will execute, but as if OMP_NESTED is set to FALSE).
 - turns out to be hard to do correctly without impacting performance significantly.

NUMTHREADS clause

 One way to control the number of threads used at each level is with the NUM_THREADS clause:

 The value set in the clause supersedes the value in the environment variable OMP_NUM_THREADS (or that set by omp_set_num_threads())

Orphaned directives

- Directives are active in the *dynamic* scope of a parallel region, not just its *lexical* scope.
- Example:

```
!$OMP PARALLEL
```

```
call claire()
```

```
!$OMP END PARALLEL
```

```
subroutine claire()
!$OMP DO
    do i = 1, n
        a(i) = a(i) + 23.5
    end do
    return
    end
```

Orphaned directives (cont)

- This is very useful, as it allows a modular programming style....
- But it can also be rather confusing if the call tree is complicated (what happens if claire is also called from outside a parallel region?)
- There are some extra rules about data scope attributes....

Data scoping rules

When we call a subroutine from inside a parallel region:

- Variables in the argument list inherit their data scope attribute from the calling routine.
- Global variables in C++ and COMMON blocks or module variables in Fortran are shared, unless declared THREADPRIVATE (see later).
- static local variables in C/C++ and SAVE variables in Fortran are shared.
- All other local variables are private.
- Reduction needs some careful consideration
 - If reduction declared at the parallel level data only correct after the parallel region
 - Declare reduction on the orphaned loop level, make reduction variable(s) shared at the parallel level

Binding rules

- There could be ambiguity about which parallel region directives refer to, so we need a rule....
- DO/FOR, SECTIONS, SINGLE, MASTER and BARRIER directives always bind to the nearest enclosing PARALLEL directive.

Thread private global variables

- It can be convenient for each thread to have its own copy of variables with global scope (e.g. COMMON blocks and module data in Fortran, or file-scope and namespace-scope variables in C/C++).
- Outside parallel regions and in MASTER directives, accesses to these variables refer to the master thread's copy.

Thread private globals (cont)

Syntax:

Fortran: **!\$OMP THREADPRIVATE** (*list*)

where list contains named common blocks (enclosed in slashes), module variables and SAVEd variables..

This directive must come after all the declarations for the common blocks or variables.

C/C++: **#pragma omp threadprivate (***list***)**

This directive must be at file or namespace scope, after all declarations of variables in *list* and before any references to variables in *list*. See standard document for other restrictions.

COPYIN clause

• Allows the values of the master thread's THREADPRIVATE data to be copied to all other threads at the start of a parallel region.

Syntax: Fortran: **COPYIN** (*list*) C/C++: **copyin** (*list*)

In Fortran the list can contain variables in THREADPRIVATE COMMON blocks.

COPYIN clause

Example:

```
common /junk/ nx
common /stuff/ a,b,c
!$OMP THREADPRIVATE (/JUNK/,/STUFF/)
nx = 32
c = 17.9
. . .
!$OMP PARALLEL PRIVATE(NX2,CSQ) COPYIN(/JUNK/,C)
nx2 = nx * 2
csq = c*c
. . .
```

if clause

- Can add if clause to:
 - parallel
 - for/do
 - sections
- if clause takes scalar expression (C/C++) or scalar logical expression (Fortran)
 - if(i)
 - if(i<100)
 - logical :: mylogical
 - ••••

if(mylogical)

if clause

```
!$OMP PARALLEL shared(b,n) private(i)if(n>100)
!$OMP DO
do i=1,n
   b(i) = b(i) * 2
end do
if(omp_in_parallel()) then
 write(*,*) `done the work in parallel'
else
 write(*,*) `done the work in serial'
end if
!$OMP END PARALLEL
```

Timing routines

OpenMP supports a portable timer:

- return current wall clock time (relative to arbitrary origin) with:
 DOUBLE PRECISION FUNCTION OMP_GET_WTIME()
 double omp_get_wtime(void);
- return clock precision with

DOUBLE PRECISION FUNCTION OMP_GET_WTICK()
double omp_get_wtick(void);

DOUBLE PRECISION STARTTIME, TIME

STARTTIME = OMP_GET_WTIME()
.....(work to be timed)
TIME = OMP_GET_WTIME() - STARTTIME

Note: timers are local to a thread: must make both calls on the same thread.

Also note: no guarantees about resolution!

Exercise

Molecular dynamics again

- Aim: use of orphaned directives.
- Modify the molecular dynamics code so by placing a parallel region directive around the iteration loop in the main program, and making all code within this sequential except for the forces loop.
- Modify the code further so that each thread accumulates the forces into a local copy of the force array, and reduce these copies into the main array at the end of the loop.
